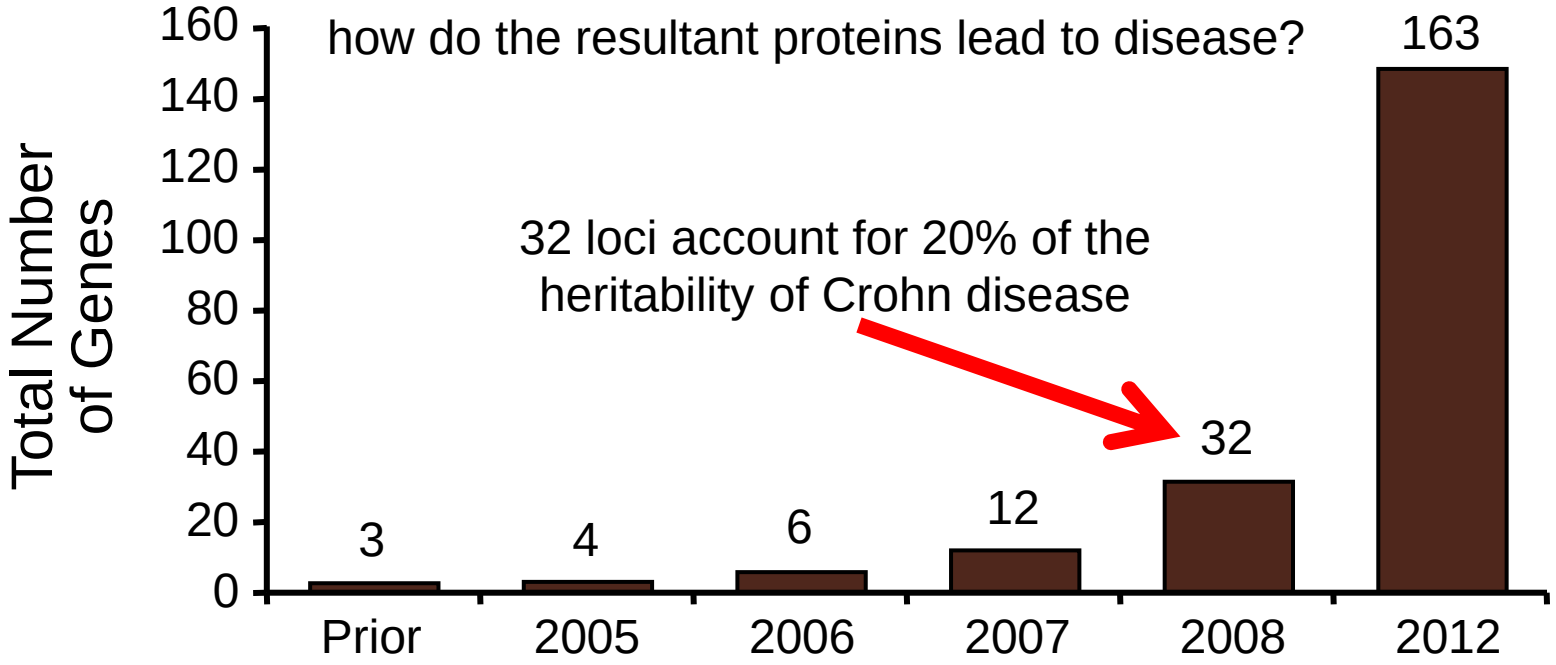
While IBD Genetics has made progress…

there is still a long way to go

how many more SNPs?
what about epigenetics?
what combinations are needed?
how do the resultant proteins lead to disease?



Barrett JC. Nat Genet 2008;40:955.
Jostins L. Nature 2012;491:119-24.

But not all genetics…

- Certainly familial
  - genetics vs epigenetics
- And monozygotic concordance > dizygotic
- But only about ½ of monozygotic twins of patients with Crohn disease will develop the disease too
  - almost all grew up together with similar but not identical environmental exposures
  - even lower for UC (~20%)

Are there predictors of IV steroid failure?

- Failure at day 3 dependent on:
  - Mean number of BMs:
    - 4-6 — 1 point
    - 7-9 — 2 points
    - >9 — 4 points
  - Albumin < 3.0 g/dL — 1 point
  - Colonic dilation — 4 points
- 85% failure rate if score > 4
- CRP on day 3 of admission
  - colectomy vs. non-colectomy, 56.6 vs 32.7; p=0.04
- Severe lesions on endoscopy (large mucosal abrasion, extensive deep ulceration, "well-like ulceration") independently predict colectomy

CYSIF trial

Summary

Background Ciclosporin and infliximab are potential rescue treatments to avoid colectomy in patients with acute severe ulcerative colitis refractory to intravenous corticosteroids. We compared the efficacy and safety of these drugs for this indication.

Methods In this parallel, open-label, randomised controlled trial, patients were aged at least 18 years, had an acute severe flare of ulcerative colitis defined by a Lichtiger score greater than 10 points, and had been given an unsuccessful course of high-dose intravenous steroids. None of the patients had previously received ciclosporin or infliximab. Between June 1, 2007, and Aug 31, 2010, patients at 27 European centres were randomly assigned (via computer-derived permutation tables; 1:1) to receive either intravenous ciclosporin (2 mg/kg per day for 1 week, followed by oral drug until day 98) or infliximab (5 mg/kg on days 0, 14, and 42). In both groups, azathioprine was started at day 7 in patients with a clinical response. Neither patients nor investigators were masked to study treatment. The primary efficacy outcome was treatment failure defined by absence of a clinical response at day 7, a relapse between day 7 and day 98, absence of steroid-free remission at day 98, a severe adverse event leading to treatment interruption, colectomy, or death. Analysis was by intention to treat. This trial is registered with EudraCT (2006-005299-42) and ClinicalTrials.gov (NCT00542152).

Findings 115 patients were randomly assigned; 58 patients were allocated to receive ciclosporin and 57 to receive infliximab. Treatment failure occurred in 35 (60%) patients given ciclosporin and 31 (54%) given infliximab (absolute risk difference 6%; 95% CI −7 to 19; p=0·52). Nine (16%) patients in the ciclosporin group and 14 (25%) in the infliximab group had severe adverse events.

Interpretation Ciclosporin was not more effective than infliximab in patients with acute severe ulcerative colitis refractory to intravenous steroids. In clinical practice, treatment choice should be guided by physician and centre experience.

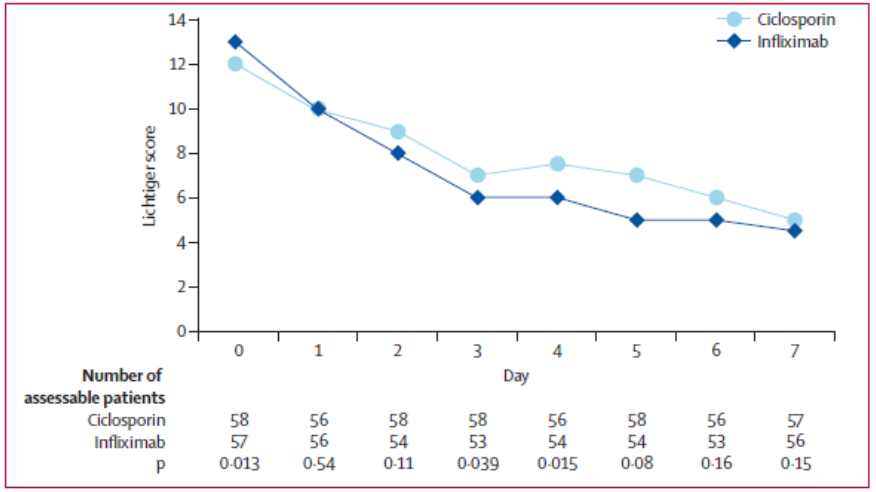

Figure 2: **Lichtiger scores from day 0 to day 7, by treatment**

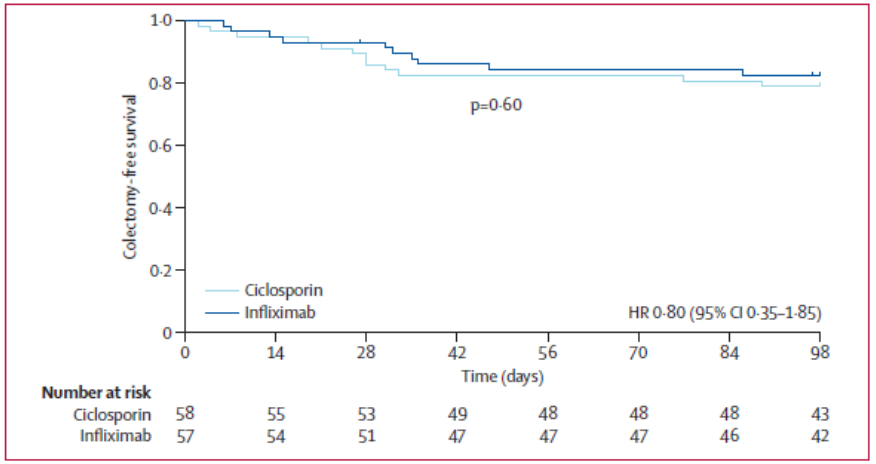

Figure 3: **Kaplan-Meier curves for colectomy-free survival**
In the infliximab group, nine patients in whom treatment was unsuccessful had rescue therapy before day 98: four were switched to ciclosporin (two colectomies), three received extra (ie, not on days 0, 14, or 42) infliximab infusions of 5 mg/kg (one colectomy), and two received scheduled infliximab infusions of 10 mg/kg (ie, a double dose on day 14 or 42; one colectomy). In the ciclosporin group, six patients in whom treatment was unsuccessful had rescue therapy before day 98: five received infliximab, including four infusions of 5 mg/kg (two colectomies) and one of 10 mg/kg (one colectomy) and we increased one patient's steroid dose (no colectomy). HR=hazard ratio.

CONSTRUCT trial

Infliximab versus ciclosporin for steroid-resistant acute severe ulcerative colitis (CONSTRUCT): a mixed methods, open-label, pragmatic randomised trial

John G Williams, M Fasih Alam, Laith Alrubaiy, Ian Arnott, Clare Clement, David Cohen, John N Gordon, A Barney Hawthorne, Mike Hilton, Hayley A Hutchings, Aida U Jawhari, Mirella Longo, John Mansfield, Jayne M Morgan, Frances Rapport, Anne C Seagrove, Shaji Sebastian, Ian Shaw, Simon P L Travis, Alan Watkins, for the CONSTRUCT investigators

Summary

Background Infliximab and ciclosporin are of similar efficacy in treating acute severe ulcerative colitis, but there has been no comparative evaluation of their relative clinical effectiveness and cost-effectiveness.

Methods In this mixed methods, open-label, pragmatic randomised trial, we recruited consenting patients aged 18 years or older at 52 district general and teaching hospitals in England, Scotland, and Wales who had been admitted, unscheduled, with severe ulcerative colitis and failed to respond to intravenous hydrocortisone within about 5 days. Patients were randomly allocated (1:1) to receive either infliximab (5 mg/kg intravenous infusion given over 2 h at baseline, and again at 2 weeks and 6 weeks after the first infusion) or ciclosporin (2 mg/kg per day by continuous infusion for up to 7 days, followed by twice-daily tablets delivering 5·5 mg/kg per day for 12 weeks). Randomisation used a web-based password-protected site, with a dynamic algorithm to generate allocations on request, thus protecting against investigator preference or other subversion, while ensuring that each trial group was balanced by centre, which was the only stratification used. Local investigators and participants were aware of the treatment allocated, but the chief investigator and analysts were masked. Analysis was by treatment allocated. The primary outcome was quality-adjusted survival—ie, the area under the curve (AUC) of scores from the Crohn's and Ulcerative Colitis Questionnaire (CUCQ) completed by participants at baseline, 3 months, and 6 months, then every 6 months from 1 year to 3 years. This trial is registered with the ISRCTN Registry, number ISRCTN22663589.

Findings Between June 17, 2010, and Feb 26, 2013, 270 patients were recruited. 135 patients were allocated to the infliximab group and 135 to the ciclosporin group. 121 (90%) patients in each group were included in the analysis of the primary outcome. There was no significant difference between groups in quality-adjusted survival (mean AUC 564·0 [SD 241·9] in the infliximab group *vs* 587·0 [226·2] in the ciclosporin group; mean adjusted difference 7·9 [95% CI −22·0 to 37·8]; p=0·603). Likewise, there were no significant differences between groups in the secondary outcomes of CUCQ scores, EQ-5D, or SF-6D scores; frequency of colectomy (55 [41%] of 135 patients in the infliximab group *vs* 65 [48%] of 135 patients in the ciclosporin group; p=0·223); or mean time to colectomy (811 [95% CI 707–912] days in the infliximab group *vs* 744 [638–850] days in the ciclosporin group; p=0·251). There were no differences in serious adverse reactions (16 reactions in 14 participants receiving infliximab *vs* ten in nine patients receiving ciclosporin); serious adverse events (21 in 16 patients *vs* 25 in 17 patients); or deaths (three in the infliximab group *vs* none in the ciclosporin group).

Interpretation There was no significant difference between ciclosporin and infliximab in clinical effectiveness.

Medical Therapy in IBD

- So the data suggest that we should:
  - Treat early
  - Treat aggressively
  - Treat with combined therapy

Symptom remission

→ Steroid-free symptom remission

→ Mucosal healing

→ Deep (histologic) remission

Are we asking for problems?

UHealth
UNIVERSITY OF MIAMI HEALTH SYSTEM
Crohn's and Colitis Center

Anti-TNF side effects

- TREAT registry of infliximab
  - Increased infection → much of that comes from steroids, narcotics, and disease severity
  - No increase in mortality
- Meta-analysis of 10 IBD trials with infliximab +/- AZA
  - No increase in infection, mortality, or malignancy
    - AZA-treated UC patients → more infections
    - AZA-treated CD patients → more malignancy

Lichtenstein G. Am J Gastroenterol 2012;107:1051-63.

UHealth
UNIVERSITY OF MIAMI HEALTH SYSTEM

UNIVERSITY OF MIAMI HEALTH SYSTEM
Crohn's and Colitis Center

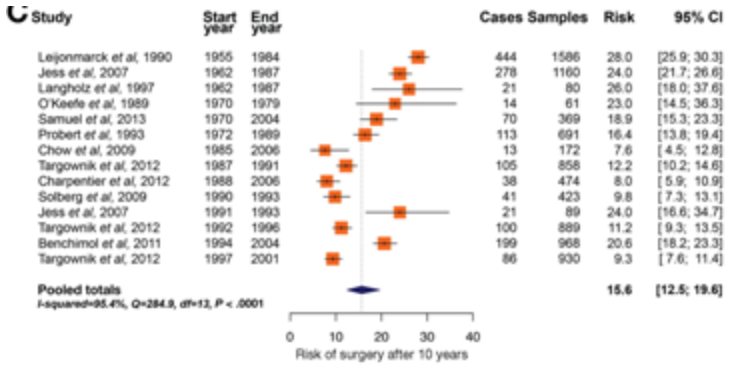
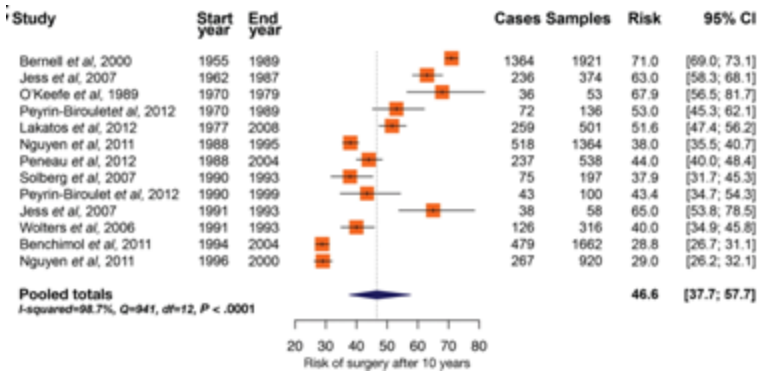
What about the risk of NOT treating?

- Rate of IBD surgeries decreasing in last 6 decades
  - Meta-analysis of 30 studies
  - Due to better/more aggressive therapy?





Frolkis AD. Gastroenterology 2013;145(5):996-1006.

UHealth
UNIVERSITY OF MIAMI HEALTH SYSTEM
Crohn's and Colitis Center

What about the risk of NOT treating?

- Decreased cancer risk by aggressively treating IBD (ulcerative colitis)
  - Danish cohort
  - 178 million patient years
  - In recent years, relative risk of colorectal cancer in UC has disappeared
    - due to more aggressive therapy?
- This decrease not seen in Kaiser study
  - But probably selected for longer duration and greater severity

Jess T. Gastroenterology 2012;143(2):375-81.
Herrington LJ. Gastroenterology 2012:143(2):382-9.

UHealth
UNIVERSITY OF MIAMI HEALTH SYSTEM
Crohn's and Colitis Center

What about the risk of NOT treating?

- Greater risk of hospitalizations and surgeries than lymphoma

Table 1. Comparing risk of lymphoma with immunomodulator therapy vs. risk of complications due to disease progression

	Azathioprine/6-mercaptopurine	Anti-TNF
Number needed to treat to cause one additional lymphoma per year with therapy	4,357 (age 20–29) 355 (age >65) (ref. 38)	2380 (ref. 56)
Number needed to cause one additional relapse per year by stopping therapy	3 (ref. 58)	
Number needed to cause one additional hospitalization per year with episodic therapy		7 (ref. 59)
Number needed to cause one additional abdominal surgery per year with episodic therapy		14 (ref. 59)

TNF, tumor necrosis factor.
Numbers adapted from referenced articles.

Surgery in IBD

Ulcerative Colitis

- Remove entire colon/rectum
  - Refractory disease
  - Colon cancer
- Options
  - Total proctocolectomy (TPC) with ileostomy
  - TPC and ileal pouch-anal anastomosis (IPAA) → 2 vs 3 stage

Crohn Disease

- Surgery does not cure
- Disease recurs after resection
- Resection of inflamed segments to treat complications (stricture, abscess, fistula) or refractory disease

UHealth
UNIVERSITY OF MIAMI HEALTH SYSTEM
Crohn's and Colitis Center

Managing Nutrition in IBD

- Malnutrition can occur in IBD
  - Decreased intake of food
    - symptoms
    - overzealous restriction
  - Decreased assimilation of nutrients
    - active disease in small intestine
  - Increased need for calories/protein (catabolic)
- Benefit from professional nutritional assessment
- Tailor diet to individual needs & preferences
- No clear "IBD diet"
- Micronutrient/macronutrient supplements

UHealth
UNIVERSITY OF MIAMI HEALTH SYSTEM
Crohn's and Colitis Center

Prevention in IBD

- Vaccinations
  - no LIVE vaccines if on an anti-TNF agent
    - intranasal influenza, MMR, yellow fever, zoster
  - otherwise routine vaccinations encouraged
    - influenza, pneumococcal, HPV
    - best uptake of vaccine BEFORE immunosuppression
- Blood Pressure monitoring → general recs
  - more so if on corticosteroids or cyclosporine
- Tobacco cessation
  - for all Crohn disease
  - for all UC once disease is controlled
    - cardiovascular and oncologic risks >> UC benefit

UHealth
UNIVERSITY OF MIAMI HEALTH SYSTEM
Crohn's and Colitis Center

Prevention in IBD

- Bone health
  - vitamin D levels
  - bone densitometry (DEXA)
    - especially if prolonged corticosteroids
- Vitamin B12 (+/- methylmalonic acid)
  - especially if ileal disease/resection, small bowel dysmotility/overgrowth
- Iron
  - unless mild probably better to replace IV (hepcidin)
- Eye Exams
  - annually
  - closer attention if on corticosteroids or concern for episcleritis/uveitis (extraintestinal manifestations)

UHealth
UNIVERSITY OF MIAMI HEALTH SYSTEM
Crohn's and Colitis Center

Prevention in IBD

- Malignancy screening
  - prostate and breast → same as general recs
  - non-melanoma skin → higher with thiopurine use
  - melanoma → higher with anti-TNF use
  - cervical and anal → increased risk
    - Pap smears, HPV, ?anal Pap smear
  - colon → depends on duration, extent, and control of disease
    - routine colonoscopies
- Depression
  - strong psychosocial effects of disease

Prevention in IBD

- Risks of immunosuppression
  - infection → **highest** with steroids
  - non-Hodgkin's lymphoma → slight increased risk
    - very low risk of hepatosplenic T-cell lymphoma (mostly thiopurine + anti-TNF in teenage males)
  - bone marrow suppression
  - liver toxicity

    thiopurines
  - reactivation of hepatitis B
  - reactivation of tuberculosis

    anti-TNFs
  - liver, lung, marrow, fetus → methotrexate
  - progressive multifocal leukoencephalopathy (PML)
    - natalizumab risk based on JC virus status and duration of treatment
  - acne, mood swings, sleep disturbance, weight gain, cataracts, osteoporosis, diabetes, poor wound healing, etc → MINIMIZE STEROIDS!!
